Some years ago I was asked to come up with some support for sandboxed apps wrt indexed data. This drummed up into Tracker 2.0 and domain ontologies, allowing those sandboxed apps to keep their own private data and collection of Tracker services to populate it.

Fast forward to today and? this is still largely unused, Tracker-using flatpak applications still whitelist org.freedesktop.Tracker, and are thus allowed to read and change content there. Despite I?ve been told it?s been mostly lack of time? I cannot blame them, domain ontologies offer the perfect isolation at the cost of the perfect duplication. It may do the job, but is far from optimal.

So I got asked again ?we have a credible story for sandboxed tracker??. One way or another, seems we don?t, back to the drawing board.
